EXPERIMENT

Flow Cytometry of the CCF-STTG1 Voltage Screen

BRANCH	DATE	EXPERIMENTER
FV	2026-09-25	Hansen Zhang

Experimental Summary

The mCherry electroporation samples were analyzed by flow cytometry 72 hours after electroporation. Seven voltage groups, from 1100 to 1400 V, were compared.

Results

Gated mCherry fluorescence increased from 1100 to 1350 V and decreased at 1400 V. The fraction outside the morphology gate increased across the voltage series, but this fraction was not a direct measure of cell death.
